Installation Notes

- Support for subversion is very limited. You can not add/manage arbitrary repositories. You can only add a repository as directly linked to an open project.
- For manual configuration, perform the installation and issue the command as root from the command line:

```
openproject configure
```

- To create the database on a remote (postgres) server, log into the remote server **before** you do the setup and issue the following commands as user psql:

```
create user openproject;
create database openproject with owner openproject;
grant all privileges on database openproject to openproject;
alter role openproject with password 'your password here';
```

- You can “zap” the database and recreate it by logging into the database server, dropping the database and recreating it.

```
drop database openproject
create database openproject with owner openproject;
grant all privileges on database openproject to openproject;
```

    - Afterwards, go to the OpenProject server and issue the following command to recreate the database tables

```
openproject reconfigure
```

- On Devuan, OpenProject will not correctly determine that it is using SysV for the init system. It tries to use systemD to perform automatic running of the daemon. I run the following command in a **screen** window (so I can see the output)

```
openproject run web
```
